

## 2-1-1 Select Operation

(1)  $\sigma_{(\text{position}='Manager') \wedge (\text{city}='London') \wedge (\text{Staff.branchNo}=\text{Branch.branchNo})}$   
(Staff X Branch)

$$(1) (1000 + 50) + 2 * (1000 * 50) = 101\ 050$$

- Read both **Staff** and **Branch** : 1000 + 50
- Compute cartesian product and write back to disk : 1000 \* 50
- Read the previous result from disk : 1000 \* 50
- Cost = (1000 + 50) + 2\*(1000\*50) = 101050

```
1 for each s in Staff:
2   for each b in Branch:
3     check if s.position='Manager' and b.city='London' and s.branchNo = b.branchNo
```

(2)  $\sigma_{(\text{position}='Manager') \wedge (\text{city}='London')}$   
Staff  $\bowtie$   $\text{Staff.branchNo}=\text{Branch.branchNo}$  Branch)

$$(2) 2 * 1000 + (1000 + 50) = 3\ 050$$

- Read both **Staff** and **Branch** : 1000 + 50
- Write **Staff join Branch** back to disk : 1000
- Read the previous result from disk : 1000
- Cost = (1000 + 50) + 2 \* 1000 = 3050

```
1 for each s in Staff:
2   for each b in Branch:
3     if s.branchNo = b.branchNo:
4       put the tuple into Temp.
5 // Temp = Staff Join Branch
6 for each s in Temp:
7   check if s.position='Manager' and s.city='London'
```

+ ☰ (3)  $(\sigma_{\text{position}='Manager'}(\text{Staff})) \bowtie_{\text{Staff.branchNo}=\text{Branch.branchNo}} (\sigma_{\text{city}='London'}(\text{Branch}))$

(3)  $1000 + 2*50 + 5 + (50 + 5) = 1160$

- Read both `Staff` and `Branch` :  $1000 + 50$
- Compute selection result and write back to disk :  $50 + 5$
- Read the previous result from disk :  $50 + 5$
- Cost =  $(1000 + 50) + 2*(50 + 5) = 1160$

```

1 // Select from S
2 for each s in Staff:
3     if s.position='Manager'
4         put s into TempS
5 // Select from B
6 for each b in Branch:
7     if b.city='London'
8         put b into TempB
9 for each s in TempS:
10    for each b in TempB:
11        check if s.branchNo=b.branchNo

```

## 2-1-2. Join Operation

- Assume  $r_1$  is R and  $r_2$  is S.
- $r_1(R)$  has 40000 tuples
- $r_2(S)$  has 30000 tuples
- 20 tuples of  $r_1$  fit in one block
- 10 tuples of  $r_2$  fit in one block.
- There are  $40000/20 = 2000$  partitions of R:  $R_1 \sim R_{2000}$
- There are  $30000/10 = 3000$  partitions of S:  $S_1 \sim S_{3000}$

Assume S and R are contiguous in storage for part a.)

## a. Nested-loops join; sorted; only 3 memory block

Assume S and R are contiguous in storage for part a.)

Outer Relation:  $S \times R$

Pseudo Code:

```
1  for each tuple s in S:
2    for each tuple r in R:
3      check if r.C = s.C
```

Block Transferred:

- For each s in S, For each r in R:  $ns * br$
- For each s in S:  $bs$
- Total:  $ns * br + bs = 30000 * 2000 + 3000 = 60003000$

Block Saught:

- For each s in S, seek R for once because it's contiguous:  $ns$
- Seek S for once: 1
- Total =  $ns + 1 = 30001$ .

## b. Nested-loops join; unsorted; 102 memory blocks

Outer Relation: S x R

Pseudo Code:

```
1  for each tuple s in S:  
2    for each tuple r in block R:  
3      check if r.C = s.C
```

Block Transferred:

- For each  $s$  in  $S$ , we still need to transfer all  $R$ :  $ns * br$
- For each  $s$  in  $S$ :  $bs$
- Total:  $ns * br + bs = 30000 * 2000 + 3000 = 60003000$

Block Saught:

- For each  $s$  in  $S$ , seek all  $R$ :  $ns * br$
- We need to seek for each block of  $S$ :  $bs$
- Total =  $ns * br + bs = 30000 * 2000 + 3000 = 60003000$ .

## c. Block Nested-loops join; unsorted; 102 memory blocks

Outer Relation: R x S

Pseudo Code:

```
1  for each group of 100 blocks in R:
2    for each block Si in S:
3      for each tuple r in group of 100 blocks in R:
4        for each tuple s in Si:
5          check if r.c = s.c
```

Block Transferred:

- We transfer 100 blocks of R for each block Si:  $(br / 100) * bs$
- For each block Ri: br
- Total:  $(br / 100) * bs + br = 20 * 3000 + 2000 = 62000$ .

Block Saught:

- We need one seek per transfer, so same as the answer above:  $(br / 100) * bs$
- For each block Ri: br
- Total:  $(br / 100) * bs + br = 20 * 3000 + 2000 = 62000$ .

## 2-2-1. 2PL

| T1        | T2        | T3        | T4        | Time |
|-----------|-----------|-----------|-----------|------|
| lock-S(B) | lock-S(B) |           | lock-S(C) | 1    |
| read(B)   | lock-S(A) |           | lock-S(A) | 2    |
|           | read(A)   |           | read(A)   | 3    |
|           | unlock(A) |           | unlock(A) | 4    |
|           | read(B)   | lock-X(A) | read(C)   | 5    |
|           | unlock(B) | Write(A)  | unlock(C) | 6    |
| lock-X(C) |           |           |           | 7    |
| unlock(B) |           |           |           | 8    |
| write(C)  |           | lock-X(B) |           | 9    |
| unlock(C) |           | write(B)  |           | 10   |
|           |           | unlock(B) |           | 11   |
|           |           | Unlock(A) |           | 12   |

- So the minimum time is 12 seconds.

## 2-2-2. Deadlock

1. Find out where deadlock happens, if any, explain why.

- 紅色: T1 被 T3 卡住
- 藍色: T2 被 T1 卡住
- 綠色: T3 被 T2 卡住
- T3 動不了，沒辦法解鎖C → T1 動不了，沒辦法解鎖A → T2 動不了，沒辦法解鎖B。就產生 deadlock了

2. Rewrite the schedule to deal with the deadlock with wait-die protocol.

- T1 比 T3 優先，所以他可以 Wait。
- T2 比 T1 後面，所以他會被 Abort，並且下次再進來 Schedule。
  - 在這個例子，他是等到 T1, T3 跑完才進去。

| T1                  | T2                      | T3        |
|---------------------|-------------------------|-----------|
| lock-X(A)           |                         |           |
| Read(A)             |                         |           |
|                     |                         | lock-X(C) |
|                     |                         | Read(C)   |
|                     | lock-X(B)               |           |
|                     | Read(B)                 |           |
| lock-S(C) (Wait T3) |                         |           |
| Read(C)             |                         |           |
|                     | lock-S(A) (Abort by T1) |           |
|                     | Read(A)                 | lock-S(B) |
|                     |                         | Read(B)   |
| Write(A)            |                         |           |
| Unlock(A)           |                         |           |
|                     |                         | Write(C)  |
|                     |                         | Unlock(C) |
|                     | lock-X(B)               |           |
|                     | Read(B)                 |           |
|                     | lock-S(A)               |           |
|                     | Read(A)                 |           |
|                     | Write(B)                |           |
|                     | Unlock(B)               |           |

3. Rewrite the schedule to deal with the deadlock with wound-wait protocol.

- T1 比 T3 優先，所以把 T3 Abort 掉。
- T2 比 T1 後面，所以他可以先等。
- T3 要等 T1, T2 跑完才會再回來。

| T1                   | T2                  | T3        |
|----------------------|---------------------|-----------|
| lock-X(A)            |                     |           |
| Read(A)              |                     |           |
|                      |                     | lock-X(C) |
|                      |                     | Read(C)   |
|                      | lock-X(B)           |           |
|                      | Read(B)             |           |
| lock-S(C) (Abort T3) |                     |           |
| Read(C)              |                     |           |
|                      | lock-S(A) (Wait T1) |           |
| Write(A)             |                     |           |
| Unlock(A)            |                     |           |
| Unlock(C)            |                     |           |
|                      | Read(A)             |           |
|                      | Write(B)            |           |
|                      | Unlock(B)           |           |
|                      |                     | lock-X(C) |
|                      |                     | Read(C)   |
|                      |                     | lock-S(B) |
|                      |                     | Read(B)   |
|                      |                     | Write(C)  |
|                      |                     | Unlock(C) |

4. Rewrite the schedule to deal with the deadlock with timestamp-based.

- T1 先進來，要 Write(A) 的時候 T2 已經 Read(A)，所以 Abort 自己。
- T2 先進來，要 Write(B) 的時候 T3 已經 Read(B)，所以 Abort 自己。
- 等 T3 跑完後 T1, T2 再進來。
- 同第一個原因，T1 Abort，然後 T2 跑完之後剩下 T1 所以就讓他跑完。

| T1                                 | T2                                 | T3       |
|------------------------------------|------------------------------------|----------|
| Read(A)                            |                                    |          |
|                                    |                                    | Read(C)  |
|                                    | Read(B)                            |          |
| Read(C)                            |                                    |          |
|                                    | Read(A)                            |          |
|                                    |                                    | Read(B)  |
| Write(A) (Abort due to T2 Read(A)) |                                    |          |
|                                    | Write(B) (Abort due to T3 Read(B)) |          |
|                                    |                                    | Write(C) |
| Read(A)                            |                                    |          |
|                                    | Read(B)                            |          |
| Read(C)                            |                                    |          |
|                                    | Read(A)                            |          |
| Write(A) (Abort again)             |                                    |          |
|                                    | Write(B)                           |          |
| Read(A)                            |                                    |          |
| Read(C)                            |                                    |          |
| Write(A)                           |                                    |          |
